airlock.

Treasury controls for cross-chain payouts

Built on Portaldot V3

MaksSay and Kuznets

Relay authority needs payout limits

A valid relay instruction can still request an unwanted payout.

Who needs this

Teams already automating treasury payouts and accepting instructions from other networks.

Airlock adds enforceable spending rules and an independent way to intervene.

Payout rules execute on Portaldot V3

01 Spending budget

The contract caps cumulative releases and preserves a reserve floor.

02 Quarantine

Larger requests wait. Funds remain reserved inside the treasury.

03 Guardian control

A separate guardian can pause releases or cancel queued requests.

Real requests and recorded results

0.25 tPOT

Paid in an earlier Sepolia-to-V3 testnet run

---

4 tPOT request

Quarantined, paused and cancelled

0 tPOT

Paid during that controlled scenario

Treasury after the controlled run: 48.75 tPOT

Inspect the recorded V3 receipts

Portaldot holds the treasury and the rules

Sepolia supplies the instruction

An outbox emits a payout request. The trusted RPC relay checks it after six canonical confirmations.

V3 enforces the payout

The Solidity contract runs through Revive. The treasury holds tPOT. The guardian signs native Substrate calls.
